

Renal care in critical cardiac patient

Prof. Hala El-Wakil

Prof of Internal Medicine and Nephrology

Faculty of Medicine, Alexandria University

Case History

- R.A.M., **66 y** old **IHD** lady, was admitted to ICU of ICC at 7th April 2014.
- Complaint: dyspnea grade 4, **orthopnea**, generalized swelling, **oliguria**.
- HPI: **frequent hospital admission** 5 times in the last 6 mo. Last one was 10 days ago when her cardiologist advised her to be admitted because of failure to parenteral diuretics, raising creatinine from **1.6 to 3.1mg/dl** and aggravation of dyspnea.

Case History

- Past history:
 - ✓ Hypertension since 20 years (no tight control).
 - ✓ Gouty on conservative therapy since 16 years.
 - ✓ Dyslipidemic since 10 years on statins.
 - ✓ IHD with open heart surgery since 7 years.
 - ✓ AF on oral anticoagulants since 7 years.
 - ✓ Renal impairment since 5 years (cr= 1.6).

Case History

- Drug history:
 - ACE inhibitor and alpha methyl dopa.
 - Anticoagulant.
 - Antiarrhythmic.
 - Statin.
 - Allopurinol and colchicine.
 - Loop diuretic with other class diuretics.

Case examination

© 2000 Todd Buck

Case examination

Edema (swelling) of the ankles and feet

Case examination

- BP= 160-70 mmHg.
- Pulse= 70 AF.
- Temp= 36.5°C axillary.
- RR=16 /min.

Case examination

- Chest: wide spread rhonchi, basal to mid-zonal fine crepitations.
- Heart: scar of cardiac surgery, AF, galloping.
- Abdomen: distension, scar of hernial repair, ascites, Peau d'orange, congested hepatomegaly.
- LL: edema, scar of venous graft.
- Neurological: anxious.
- Musculoskeletal examination: OA of both knee, obesity (BMI =31).

Case examination

- UOP= 20 ml/h.
- Concentrated urine

Investigations

- Creatinine= 1.6- 3.1.
- B urea=170.
- S uric acid= 7.7.
- K= 5.5
- S albumin= 3.2.
- Hb%= 10.5 NN.
- Urine: albumin +, RBCS=15.
- INR= 3.2.

Radiology

- Abdominal US: fatty liver, normal kidneys, ascites.
- Echo: diastolic dysfunction, MR, EF=30%.
- Chest x ray

Renal problems in this lady

- AKI on top of CKD.
- What is volume status management? (hypo or hyper).
- What is ideal RRT if needed?

Renal problems in this lady

- What is volume status management? (hypo or hyper).
- What is ideal RRT if needed?

AKI on top of CKD

- CKD based on GRF estimation (e GFR by CKD EPI = 33.2ml/min)

Prognosis of CKD by GFR and Albuminuria Categories: KDIGO 2012				Persistent albuminuria categories Description and range		
				A1	A2	A3
				Normal to mildly increased	Moderately increased	Severely increased
				<30 mg/g <2 mg/mmol	30-300 mg/g 3-30 mg/mmol	>300 mg/g >30 mg/mmol
GFR categories (ml/min/1.73 m ²) Description and range	G1	Normal or high	≥90	Green	Yellow	Orange
	G2	Mildly decreased	60-89	Green	Yellow	Orange
	G3a	Mildly to moderately decreased	45-59	Yellow	Orange	Red
	G3b	Moderately to severely decreased	30-44	Orange	Red	Red
	G4	Severely decreased	15-29	Red	Red	Red
	G5	Kidney failure	<15	Red	Red	Red

Green: low risk (if no other markers of kidney disease, no CKD); Yellow: moderately increased risk; Orange: high risk; Red, very high risk.

AKI on top of CKD

- AKI based on creatinine and GRF deterioration

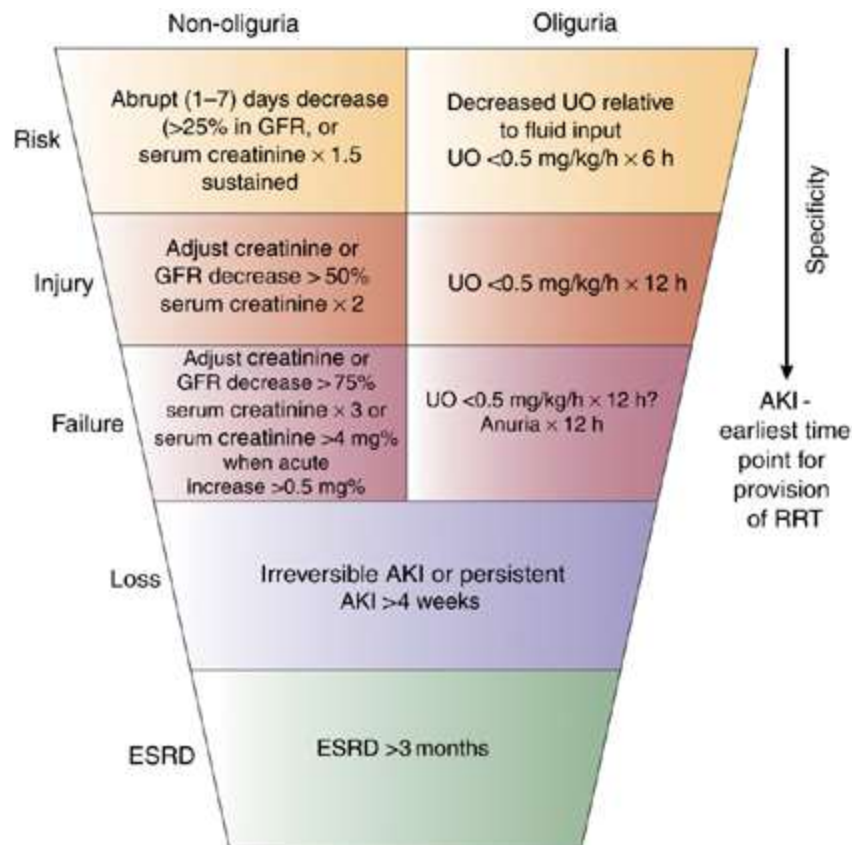

Figure: Rifke Criteria for Diagnosis of AKI

AKI on top of CKD

- AKI based on creatinine and GRF deterioration

RIFLE Criteria

Risk	Increased creatinine x1.5 or GFR decrease > 25%	UO < 0.5ml/kg/h x 6 hr	High Sensitivity
Injury	Increased creatinine x2 or GFR decrease > 50%	UO < 0.5ml/kg/h x 12 hr	
Failure	Increase creatinine x3 or GFR decrease > 75%	UO < 0.3ml/kg/h x 24 hr or Anuria x 12 hrs	High Specificity
Loss	Persistent ARF = complete loss of kidney function > 4 weeks		
ESKD	End Stage Kidney Disease		

AKIN Criteria

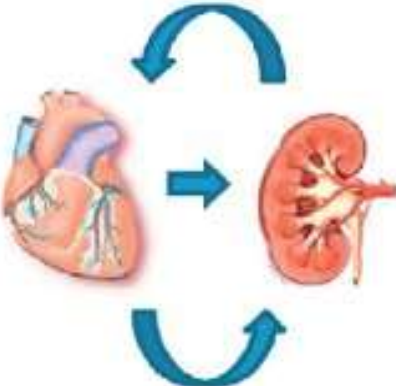

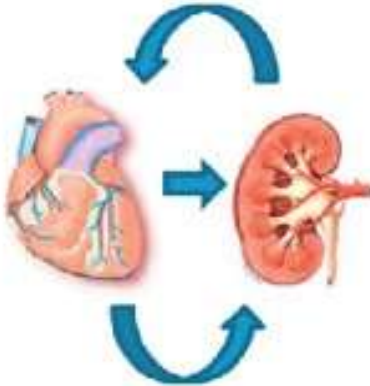

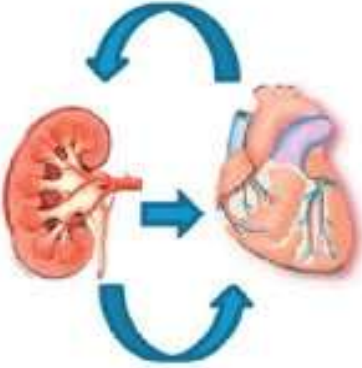

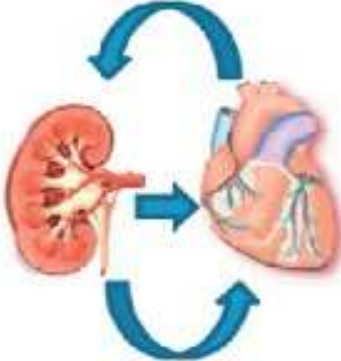

Stage 1	Serum creatinine increase ≥ 0.3 mg/dl OR increase to 1.5–2.0-fold from baseline	<0.5 ml/kg/h for 6 h
Stage 2	Serum creatinine increase 2.0–3.0-fold from baseline	<0.5 ml/kg/h for 12 h
Stage 3	Serum creatinine increase >3.0-fold from baseline OR serum creatinine ≥ 4.0 mg/dl with an acute increase of at least 0.5 mg/dl	<0.3 ml/kg/h for 24 h OR anuria for 12 h

AKI in a cardiac patient

Cardiorenal syndrome

- **Cardio-renal syndrome** means declining renal function in the setting of advanced CHF.

Types of CRS

	Chronic	Acute
Cardiorenal	 <p>Type II CRS</p>	 <p>Type I CRS</p>
Renocardiac	 <p>Type IV CRS</p>	 <p>Type III CRS</p>

Figure 5 CRS Type 5

Pathophysiological interactions between heart and kidney in type 5 cardiorenal syndrome (CRS) or "secondary CRS"

(systemic condition, e.g., diabetes mellitus, sepsis, causing both cardiac and renal dysfunction). LPS = lipopolysaccharide (endotoxin); RVR = renal vascular resistance. Figure illustration by Rob Flewell.

Table 1. CRS

General definition

Pathophysiologic disorder of the heart and kidneys whereby acute or chronic dysfunction in one organ induces acute or chronic dysfunction in the other

CRS type I (acute CRS)

Abrupt worsening of cardiac function leading to AKI

CRS type II (chronic CRS)

Chronic abnormalities in cardiac function causing progressive and permanent chronic kidney disease

CRS type III (acute renocardiac syndrome)

Abrupt worsening of renal function causing acute cardiac disorders

CRS type IV (chronic renocardiac syndrome)

Chronic kidney disease contributing to decreased cardiac function, cardiac hypertrophy, and/or increased risk of adverse cardiovascular events

CRS type V (secondary CRS)

Systemic condition (eg, diabetes mellitus, sepsis) causing both cardiac and renal dysfunction

CRS-Type 1

Figure 1 CRS Type 1

Pathophysiological interactions between heart and kidney in type 1 cardiorenal syndrome (CRS) or "acute CRS" (abrupt worsening of cardiac function, e.g., acute cardiogenic shock or acute decompensation of chronic heart failure) leading to kidney injury. ACE = angiotensin-converting enzyme; ANP = atrial natriuretic peptide; BNP = B-type natriuretic peptide; CO = cardiac output; GFR = glomerular filtration rate; KIM = kidney injury molecule; N-GAL = neutrophil gelatinase-associated lipocalin; RAA = renin angiotensin aldosterone. Figure illustration by Rob Flewell.

Figure 2. Hemodynamic mechanisms activated in CRS type 1.

- **Blood Volume**
- **Blood Pressure**

BALANCE

Fluid Balance

Daily fluid input:

- 1.5-2.0 L maintenance
- 1.5-2.5 L medications
- 0.8-1.5 L nutrition
- 0.5-1.5 L boluses

Daily fluid output:

- 1.0-2.0 L Urine
- 1.0-2.0 L Insensible losses
- 1.0-3.0 L Dialysis/ UF
- 0.5-1.5 L Other

Body Composition

Figure 3. Compensatory mechanisms in HF.

A continuous compromise

How to handle a delicate balance?

Daily fluid input:

1.5-2.0 L
maintenance
1.5-2.5 L
medications
0.8-1.5 L nutrition
0.5-1.5 L boluses

Daily fluid output:

1.0-2.0 L Urine
1.0-2.0 L Insensible
losses
1.0-3.0 L Dialysis/
UF
0.5-1.5 L Other

- In what clinical circumstances? AKI, CRS, SEPSIS, CKD, Dialysis
- How much fluid to give, How fast, What type of fluid? Physiological targets?
- How much fluid to remove, How fast, What modality? (Diuretics VS Dialysis)

Optimal fluid status is
our target

Figure 4. Components of fluid balance calculation and fluid distribution in the body.

How should we manage fluids in patients who develop AKI?

Infusions

Diuretics

Extracorporeal ultrafiltration

Blood Volume and hemodynamics

Fluid balance prescription

Fluid exchange prescription

Fluid balance errors

Why are fluids given?

Daily fluid input:

1.6 ± 0.2 L	maintenance fluids
1.8 ± 0.4 L	medications
0.8 ± 0.3 L	nutrition
0.5 ± 1.2 L	fluid boluses

Diuretics

- Diuretics can be given to test renal responsiveness after adequate fluid loading
- Diuretics should be discontinued or at least modulated and tailored to each patient if there is no response to avoid side effects.
- There is no evidence that diuretics reduce morbidity or mortality or improve renal outcome
- If urine production is restored, this greatly facilitates fluid management.

The monthly thought of the Editor

Early goal directed therapy and early goal ultrafiltration therapy for critically ill patients with acute kidney injury

Very few people in the world of intensive care medicine have not heard about the Emanuel Rivers Study describing the fluid management approach defined as early goal directed therapy. The study basically concludes that a thorough fluid resuscitation policy guided by hemodynamic monitoring and central venous oxygen saturation in the first six hours of hospital admission is a procedure that improves survival in patients with severe sepsis and septic shock. Early goal directed therapy includes crystalloids or colloids based on CVP measurement, vasoactive agents based on mean arterial

amounts of fluid for resuscitation purposes.

All these observations have pointed out one important aspect of the patients with sepsis and septic shock: the fluid balance is remarkably positive in the first hours of ICU admission. But positive fluid balance has its price: first of all, fluid given in the presence of damaged endothelium and loss of plasma oncotic power makes a real float of the interstitium with swelling of tissues and cells; furthermore, cardiac contractility might be impaired and the fluid overload further contributes to myocardial dysfunction due to hypervolemia. Third, these patients are often oliguric

Treatments for extracorporeal volume removal

Technique

- Ultrafiltration
- Hemofiltration
- Hemodialysis
- Hemodiafiltration

Frequency

- Isolated
- Intermittent
- Daily
- Continuous

Electrolyte disorders might be worsened by aggressive hemodialysis while they can be progressively corrected by CRRT

INTERMITTENT HEMODIALYSIS

CONTINUOUS HEMOFILTRATION

Aquapheresis Therapy

- Therapy to **safely achieve euvoemia** (dry weight)
- Uses a simplified form of ultrafiltration
 - Quick and easy device setup: less than 10 mins
 - Low blood flow: 20-40 mL/min
 - Low blood volume: **33 mL**
 - Precise fluid removal rates: 10-500 mL/hour
- **Inpatient** or **outpatient** settings
 - ICU, CCU, MICU, telemetry, stepdown, observation, ED, outpatient clinics
- **Peripheral** or **central** venous access
 - Flexible access sites and catheters
- Diverse physician prescription
- **No clinically significant impact on electrolyte balance, blood pressure or heart rate**

Think of it as a “mechanical diuretic”...

- Ultrafiltration has been available for decades with CVVH devices
- How often are **non-renal, fluid overloaded heart failure patients** currently treated with CVVH just to remove excess volume?
- Why?

	Aquapheresis	CVVH
Patient	Fluid overload	Renal
Treatment Venue	Inpatient/Outpatient	ICU
Blood Withdrawal Rates	10 – 40 mL/min.	100 – 300 mL/min.
Extracorporeal Volumes	33 mL	100 – 300 mL
Venous Access	Peripheral or Central	Central

Balance Summary

- Patient's balance is crucial
- Use fluid with great caution
- Consider kidney function
- Use diuretics with individualized modality
- You might be required to remove fluids by Ultrafiltration or other CRRT techniques
- Treatment with extracorporeal techniques should be timely instituted and accurately performed (error-free).
- Techniques are not all the same

Biomarkers

Table 1**Protein Biomarkers for
the Early Detection of Acute Kidney Injury**

Biomarker	Associated Injury
Cystatin C	Proximal tubule injury
KIM-1	Ischemia and nephrotoxins
NGAL (lipocalin)	Ischemia and nephrotoxins
NHE3	Ischemia, pre-renal, post-renal AKI
Cytokines (IL-6, IL-8, IL-18)	Toxic, delayed graft function
Actin-actin depolymerizing F	Ischemia and delayed graft function
α -GST	Proximal T injury, acute rejection
π -GST	Distal tubule injury, acute rejection
L-FABP	Ischemia and nephrotoxins
Netrin-1	Ischemia and nephrotoxins, sepsis
Keratin-derived chemokine	Ischemia and delayed graft function

GST = glutathione S-transferase; IL = interleukin; KIM = kidney injury molecule; L-FABP = L-type fatty acid binding protein; NGAL = neutrophil gelatinase-associated lipocalin; NHE = sodium-hydrogen exchanger.

 - Pre-Load parameters
 - Volume responsiveness (SPV, PPV)
 - Non-Invasive
 - Echocardiography
 - Bioimpedance Spectroscopy

Optimal Hydration: How to get there?

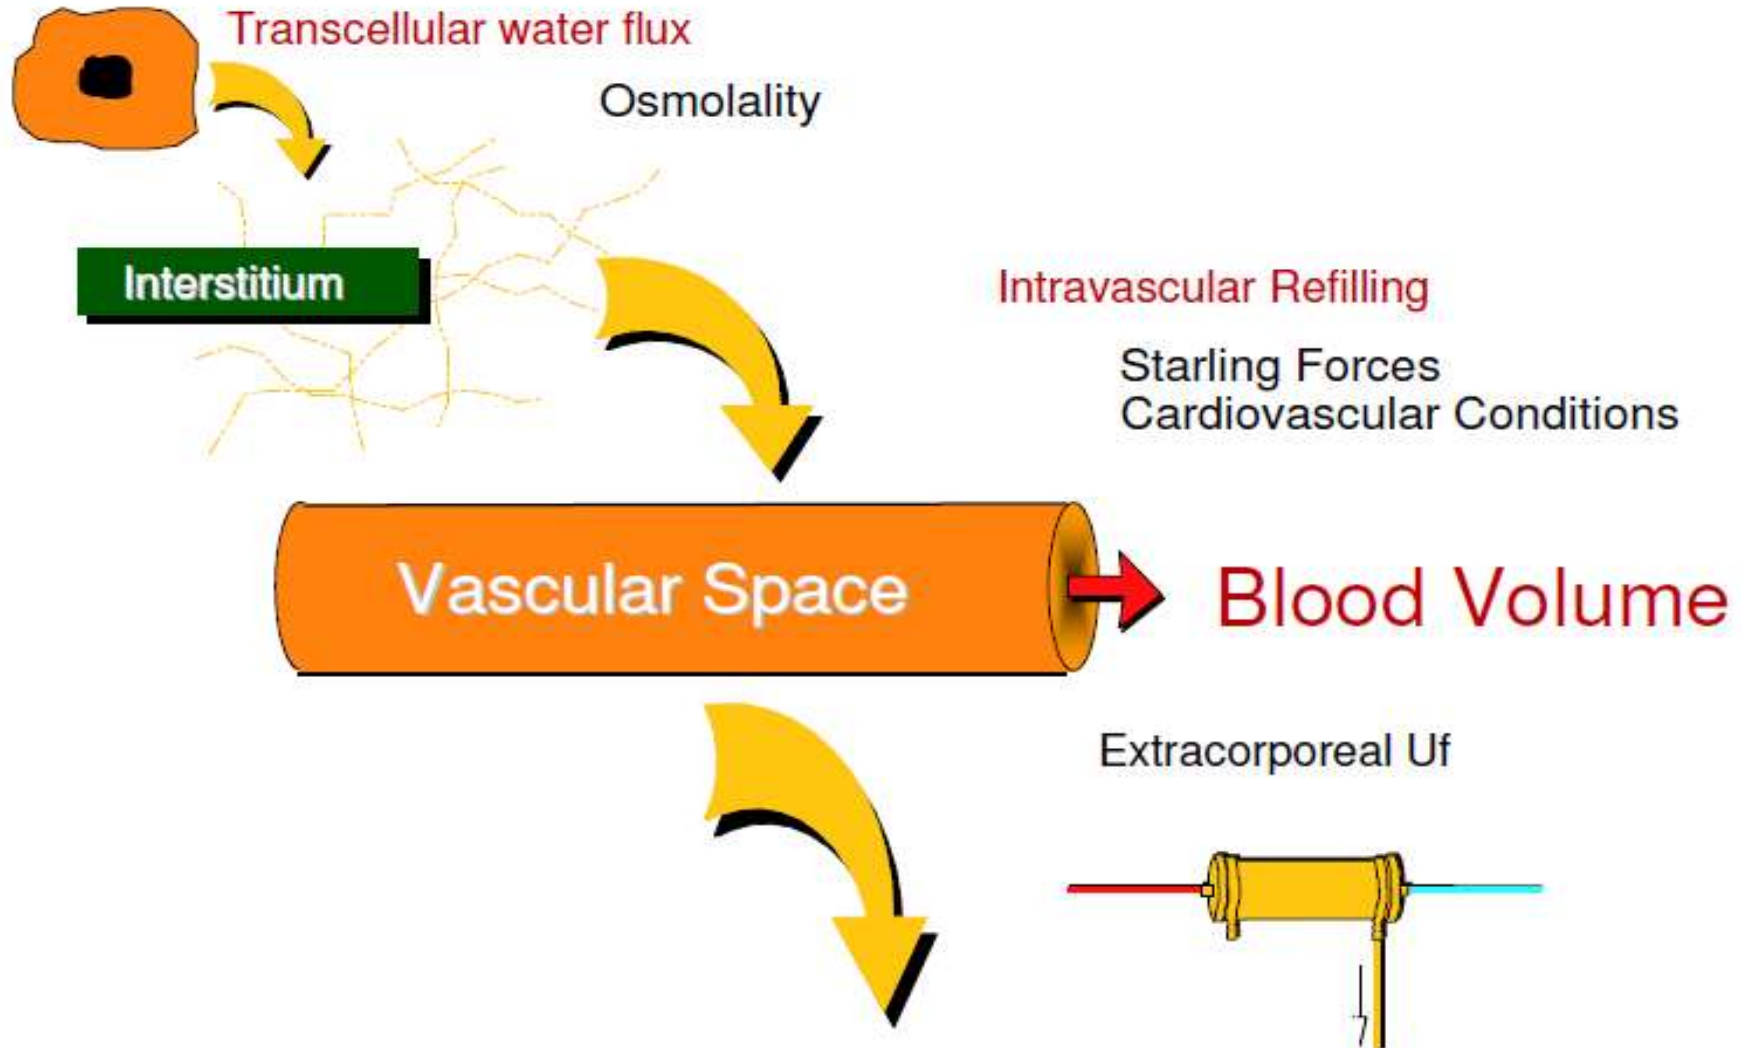

Blood Volume

BLOOD VOLUME = U_f - Refilling

Blood Pressure

Blood pressure

- Blood pressure, as a measure of volume status, is a poor and late changing indicator.
- Orthostatic vital signs combine dynamic gravity induced changes in pulse and blood pressure that occur as a consequence of volume movement resulting from postural change.

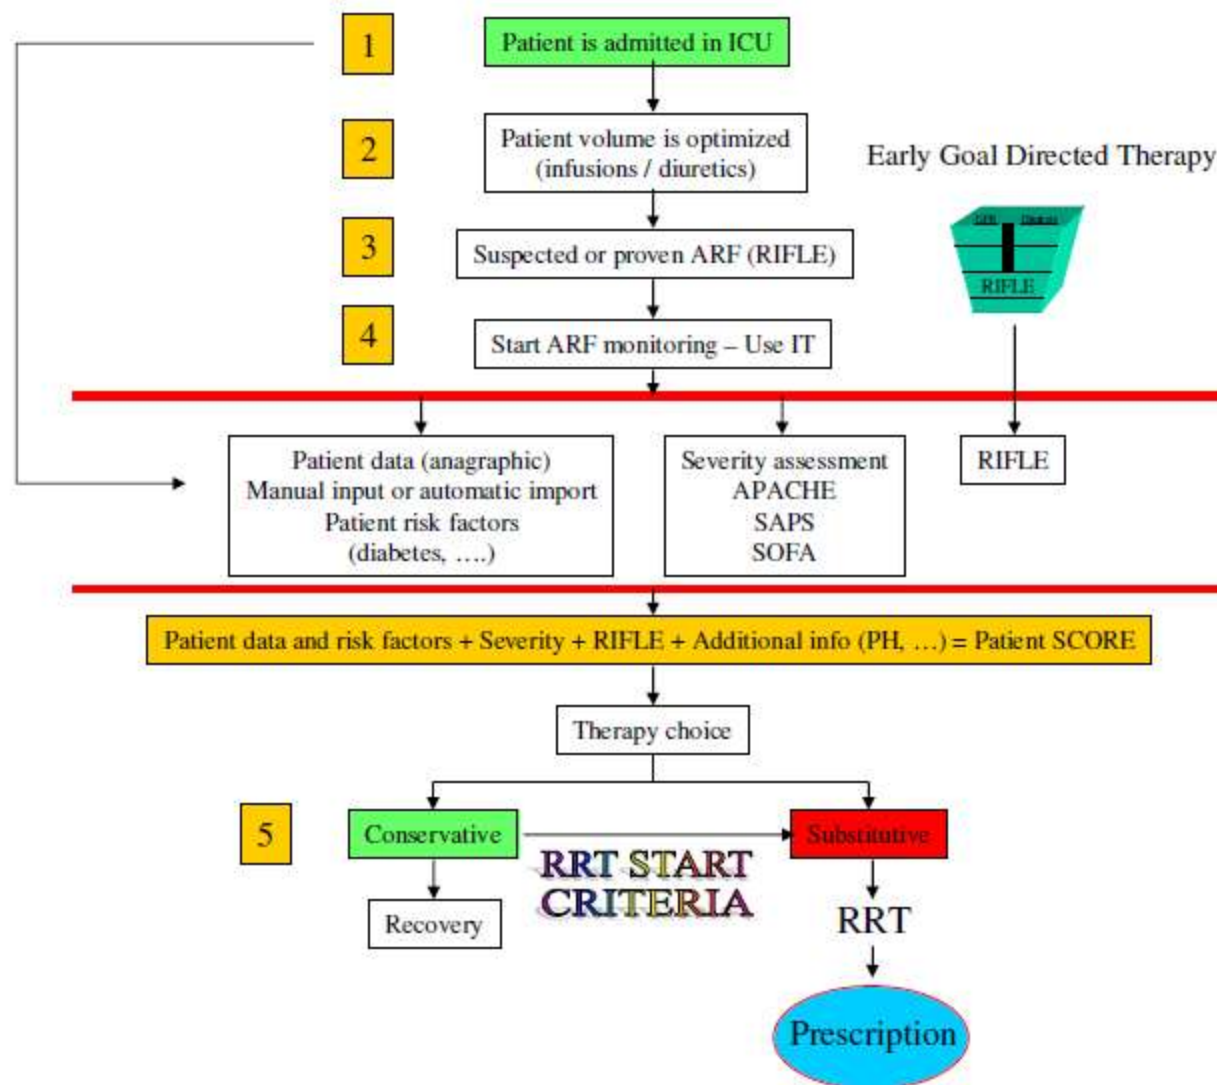

Hemodynamic response

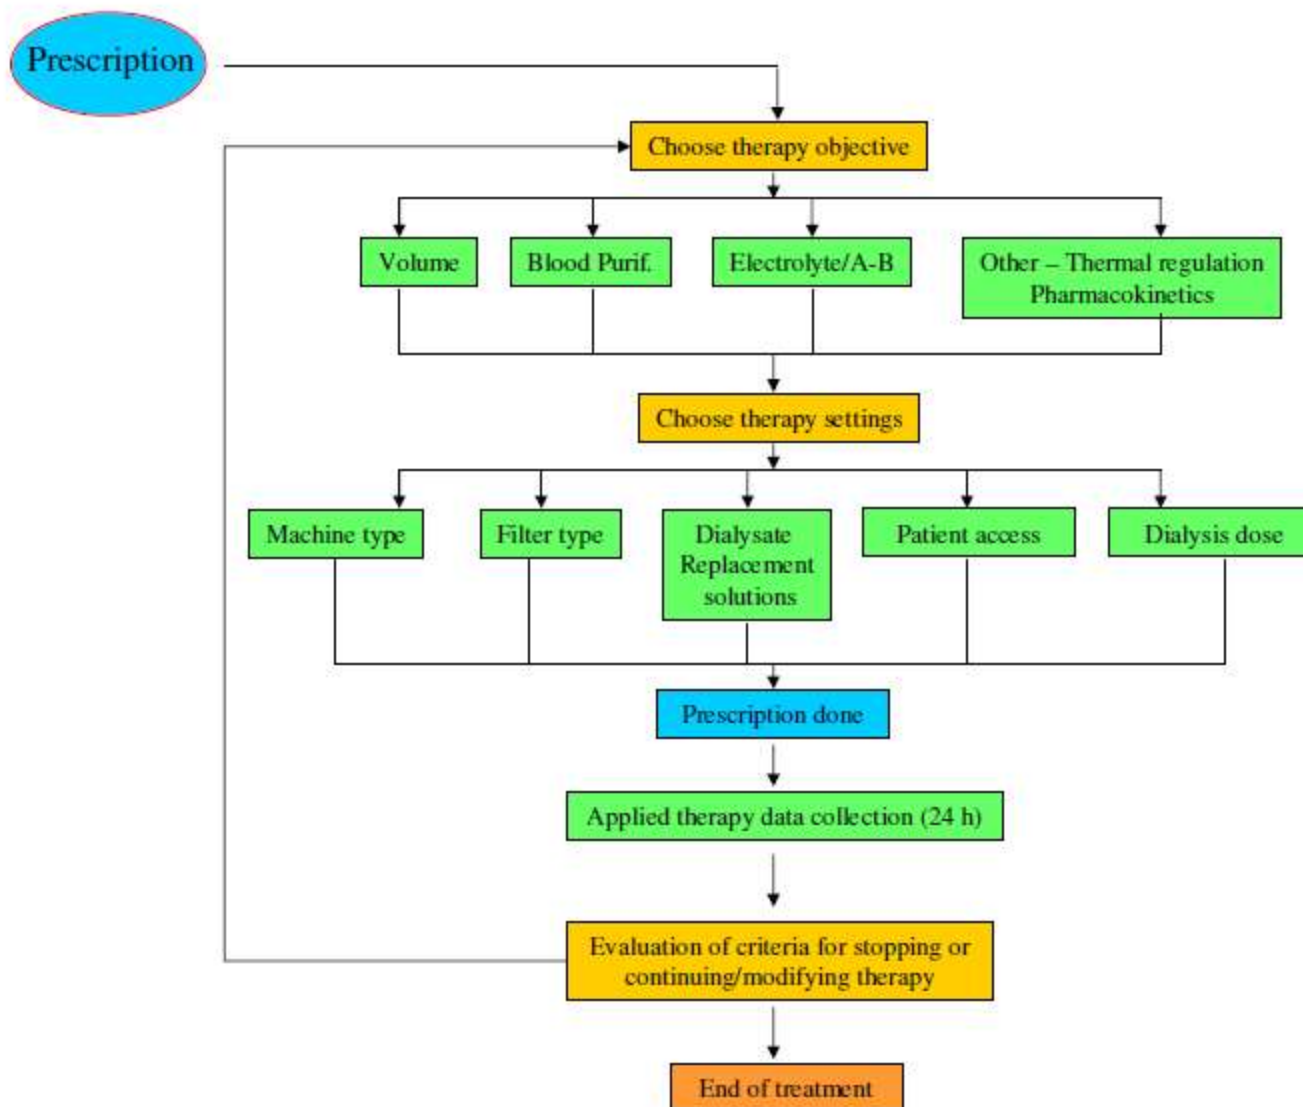

Renal problems in this lady

- AKI on top of CKD.
- What is volume status? (hypo or hyper).
- What is ideal RRT if needed?

FROM ADMISSION TO PRESCRIPTION IN FIVE STEPS

1

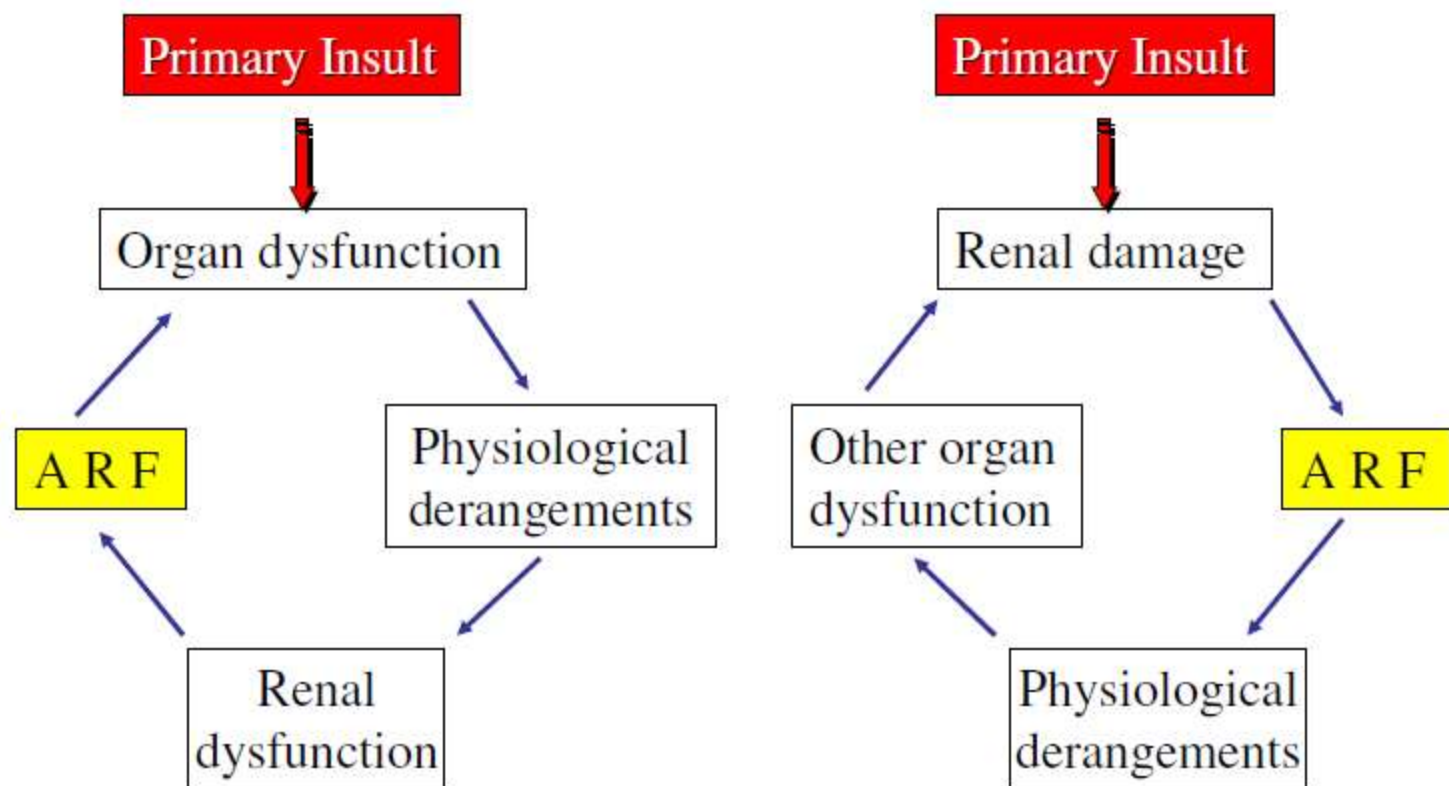

Patient is admitted in ICU

Every patient admitted in the intensive care unit (ICU) is at high risk of developing single or multiple organ failure (MOF)

- defects in organ perfusion
- reduction in mean arterial pressure
- toxic effect of inflammation and sepsis.

An ongoing matter of debate is if kidneys are victims of MOF or have a primary role in causing it.

The Kidney in MOF: culprit or victim ?

Sepsis

Hemodynamic
changes

Various
Toxins

Pre- Renal

Renal cell injury

2

VOLUME OPTIMIZATION

THE MOST EFFECTIVE FORM OF RENAL PROTECTION AND ARF PREVENTION

Volume

The lung: Wet you die, Dry you fly
The Kidney : Dry you die, wet you pee

INTRAVASCULAR VOLUME EXPANSION

Bernsten et Al 1995
Solomon et Al 1994
Sort et Al 1999

Scientific evidence that intravascular fluid expansion is nephroprotective.

Albumin
in liver
patients

How, how much and when?

Crystalloids
versus
Colloids

No data available to indicate that a certain degree of intravascular filling is more protective to the kidney with early pre-renal dysfunction than a lesser degree of intravascular filling (e.g. RAP >15 mmHg vs 12 or 10 mmHg). Clinical judgement is still important and it should integrate data.

Keeping the bottles on the shelf

Watch carefully for
pseudo-ARDS

- There is no scientific case for fluid administration if $CI > 2.5 \text{ L/min/m}^2$ without inotropes
- If CI is high and the patient is hypotensive, they need vasopressors not fluids, irrespective of CVP/PAOP/LVEDV etc.
- Pursuing supranormal values is pointless and dangerous
- Be careful with the bleeding patient

3

Suspected or proven ARF

4

Start ARF monitoring

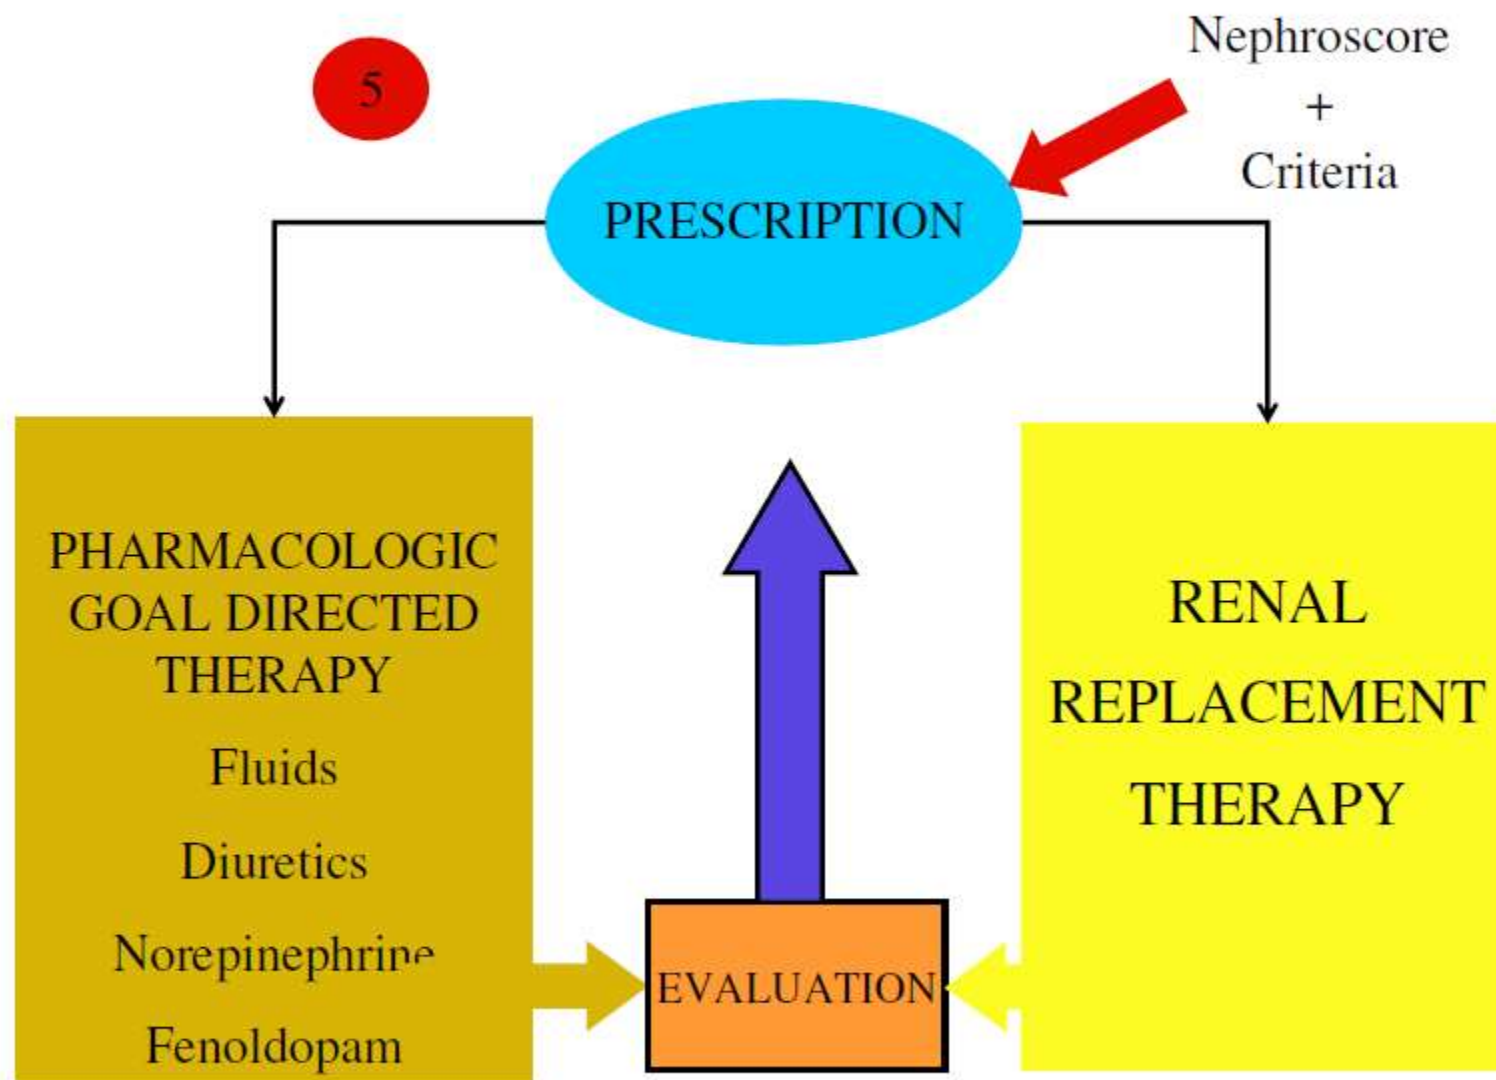

Disparate clinical data are needed and the patient must be evaluated
under all aspects

Start IT ASSESSMENT

Anagraphical and clinical data

Severity assessment (SAPS APACHE TISS SOFA RIFLE)

NEPHRO SCORE

The Goal

Augmentation of perfusion pressure and oxygenation using both appropriate volume expansion and catecholamines.

The precise blood pressure targeted depends on premonitory blood pressure and individual responses but often map 90 - 100 mm hg.

The benefits of vasopressors balanced against potential adverse effects such as myocardial ischemia or tachyarrhythmia

Starting treatment of A R F

How aggressive should the treatment be ?

How early should the treatment start?

What should be the criteria for initiating RRT?

**Disease
related
risks**

**Treatment
related
risks**

Do we have standard criteria and fixed reference numbers?

RRT in the ICU: STARTING CRITERIA

- Anuria - Oliguria (diuresis ≤ 200 ml in 12 h)
- Severe metabolic acidosis ($\text{pH} < 7.10$)
- Hyperazotemia ($\text{BUN} \geq 80$ mg/100 ml)
- Hyperkalemia ($\text{K}^+ \geq 6,5$ mEq/L)
- Clinica signs of uremic toxicity
- Severe Dysnatremia ($\text{Na}^+ \leq 115$ o ≥ 160 mEq/L)
- Hyperthermia
- Anasarca or severe fluid overload
- Multiple Organ Failure including renal dysfunction
- SIRS, Sepsis or Septic shock with renal dysfunction

ADEQUACY / DOSE

Clearance: Marker Molecule – Treatment modality

High Efficiency - Low K_c

Freq

Low Efficiency - Low K_c

High Efficiency - High K_c

Low Efficiency - High K_c

Adequate Renal Replacement in the ICU

What is treatment dose?

Treatment dose can be defined by:

Efficiency = Inst. Clearance (K)

{ Intensity = Clearance x time (Kt)

{ Frequency = Days/week - Continuous

Efficacy = $Kt/V_{sp} - Kt/V_{eq} - StdKt/V$

Efficiency (K) (Instant. Clearance)

ml/min

K depends on:

Q_b , Q_d , Q_f ,

Reference molecule

Hemodialyzer type

Intensity ($K \times t$) (Daily Clearance)

$[(\text{ml/min}) \times \text{min})] = \text{ml}$

Intensity x Frequency ($K \times t \times d/w$)

(Weekly Clearance) $[(\text{ml/min}) \times \text{min}) \times d] = \text{ml/week}$

Efficacy: Fractional Clearance ($K \times t / V$)

K = Average Clearance during treatment

t = Treatment time

V = Urea distribution volume (TBW)

UREA KINETICS and VOLUME

Amount disappeared from blood > amount appeared in dialysate, i.e. blood-based vs dialysate-side kinetics overestimates urea removal. *Evanson JA et Al, Kidney Int 1999; 55:1501-1506.*

QUANTITATIVE BLOOD PURIFICATION

Example

D short HD

$K = 200 \text{ ml/min}$

Urea $[C]_o = 110 \text{ mg/dl}$

Urea $[C]_t = 30 \text{ mg/dl}$

Tx time = 180 mins

$Kt/V = 1.12$

Tot. Clear. = 36 L

Urea removed = 18 g

Rebound = 22 %

D Ext. HD

$K = 80 \text{ ml/min}$

Urea $[C]_o = 110 \text{ mg/dl}$

Urea $[C]_t = 30 \text{ mg/dl}$

Tx time = 480 mins

$Kt/V = 1.24$

Tot. Clear. = 38.4 L

Urea removed = 27 g

Rebound = 6 %

CVVHD

$K = 30 \text{ ml/min}$

Urea $[C]_o = 70 \text{ mg/dl}$

Urea $[C]_t = 65 \text{ mg/dl}$

Tx time = 1440 mins

$Kt/V = 0.9$

Tot. Clear. = 43.2 L

Urea removed = 33.6 g

ADEQUACY / DOSE

Clearance: Marker Molecule – Treatment modality

Fixed: Standard = 2 L/h
High Vol. = > 3 L/h

Personalized: Standard = 30-35 ml/h/Kg b.w.
High Vol. = 45 ml/h/Kg b.w.

In CVVH → ml/min or L / 24 h

Why $U_f = T_x$ Dose in CVVH ?

$$\text{Clearance in the human kidney (K)} = \frac{[U] \times V}{[P]}$$

$$\text{Clearance in the hemofilter (K)} = \frac{[U_f] \times Q_f}{[P]}$$

Where: $[U_f]/[P] = \text{Sieving Coefficient (S)}$

$$\text{Urea K} = \frac{[U_f] \times U_f}{[P]} = \frac{80 \times 35}{80} = 35 \text{ ml/min}$$

Constant?

Patient X.Y. = Actual Body Weight 65 Kg

Estimated Fluid Overload = 5 Kg

Early Ultrafiltration  Target B.W. = 60 Kg

Estimated V = 36 Liters

48 L/24h = Kt/V : 1.3

Target is 2L/h or 33 ml/min

Placement of Adequate Vascular Access

Time = 24 h (Downtime foreseen? K adjustment!)

Machine = equipment capable to perform Tx (availability?)

Blood Flow = 180 ml/min (Filtration Fraction 25%)

Replacement Solution = See Acid-base and Electrolytes

Target is 2L/h or 33 ml/min

CVVH = ultrafiltration equals clearance (post-dil.)

CVVHD = dialysate flow equals clearance only for
small molecules and for a 100%
saturated effluent (depends on filter)

CVVHDF = Clearance depends on ultrafiltration,
site of replacement, dialysate flow rate
and its saturation.

DELIVERED AND PRESCRIBED CLEARANCE

Factors affecting discrepancy

- Blood flow rate lower than that displayed by the dialysis machine
 - Inadequate vascular access
- Dialysate/ Filtrate flow lower than that displayed by the dialysis machine. Excessive filtration fraction
- Inadequate performance of the hemofilter-hemodialyzer
 - Incorrect priming procedures
 - Loss of surface area (clotting, air)
 - Loss of permeability (clogging of the membrane)
 - High blood viscosity and hematocrit
 - Excessive filtration fraction

☒ Predilution

☐ Postdilution

Qb=60-200 ml/min Qr=8-12 ml/min Qd=10-20 ml/min (K=20-40 L/24hr)
 Technique whereby blood is driven through a highly permeable dialyzer and a counter-current flow of dialysis solution is delivered on the dialysate compartment. The ultrafiltrate produced during membrane transit is in excess to the patient weight loss. Solute clearance is obtained both by diffusion and convection. Replacement solution is needed to obtain fluid balance.
 Efficiency is extended from small to larger molecules

Qb=50-200 ml/min Qr=4-25 ml/min Qd=12-30 L/24hr
 Technique whereby blood is driven through a highly permeable dialyzer and ultrafiltrate is produced during membrane transit. The ultrafiltrate produced during membrane transit is added to patient's ultrafiltrate to achieve fluid balance and replace losses. Ultrafiltration is a process of patient weight loss and replacement is needed.
 Clearance for all solutes equals ultrafiltration

Back to menu

SCUF

[Back to menu](#)

$Q_b=50-100$ ml/min $Q_f=2-5$ ml/min

Technique where blood is driven through a highly permeable filter via an extracorporeal circuit in veno-venous mode. The ultrafiltrate produced during membrane transit is not replaced and it corresponds exactly to the patient weight loss.

Used only for fluid control in overhydration status

Input Fluid Balance Data				Output Data		Results
SCUF		Treatment time per day	12 0	hr min	Removal	3600 ml/day
		Ultrafiltration rate	300	ml/hr		
Non CRRT	Fluid input	Parenteral	2000	ml/day	Repletion	1800 ml/day
		Enteral	500	ml/day		
	Fluid output	Urine	100	ml/day		
		GI tract loss	100	ml/day		
		Insensible loss	500	ml/day		
		Others	0	ml/day		
Total Fluid Balance Per Day				Removal	1800 ml/day	

CVVH

Blood flow rate	150	ml/min
Treatment time per day	24	hr
		min
Predilution replacement rate	1850	ml/hr
Ultrafiltration rate	2000	ml/hr
Fluid balance: Removal	150	ml/hr

Optional Data

Instantaneous urea clearance calculation *

☒ Option 1: Simultaneous blood samples
☐ Option 2: Simultaneous blood and ultrafiltrate samples

Cbi	60	mg/dl
Cbo	50	mg/dl

Daily urea removal and SRI calculation

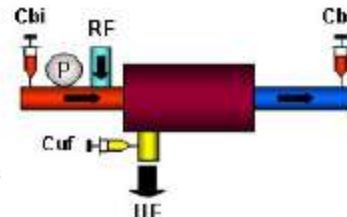

Steady state Cbi ** 60 mg/dl
 Start of the day Cbi 60 mg/dl

Urea generation rate calculation ***

☒ Option 1: Blood and ultrafiltrate samples
☐ Option 2: Blood samples
☐ Option 3: Ultrafiltrate samples

Cbi at time 0	60	mg/dl
Cbi at time t	60	mg/dl
Cuf at time 0	60	mg/dl
Cuf at time t	60	mg/dl
Duration between 2 sampling (Time 0 to t)	24	hr
		min
Body weight at time 0	70	kg
Body weight at time t	68.2	kg
Urine volume (Time 0 to t)	300	ml
Average urine urea nitrogen	500	mg/dl

☒ Predilution
☐ Postdilution
☐ Pre + Postdilution

Ob=50-200 ml/min Qf=0-25 ml/min (K=12-36 L/24hr)
 Technique whereby blood is driven through a highly permeable filter via an extracorporeal circuit in veno-venous mode. The ultrafiltrate produced during membrane transt is replaced in part or completely to achieve blood purification and volume control. Ultrafiltration is in excess of patient weight loss and replacement is needed.
Clearance for all solutes equals ultrafiltration

Output Data	Results
Instantaneous urea clearance K	24.35 ml/min
Estimated V BW x 0.6	42.00 litre
K/BSA K / BSA	12.91 ml/min.m ²
Daily urea clearance K x t	35076 ml/day
Daily Kt/V K x t / V	0.84
Daily urea nitrogen removal K x t x Cbi	21.05 g/day
Daily solute removal index SRI	0.84
Weekly urea clearance K x t x d/wk	245532 ml/week
Weekly urea nitrogen removal K x t x Cbi x d/wk	147.32 g/week
Weekly solute removal index SRI x d/wk	5.85
Residual renal urea clearance Kr	1.74 ml/min
Urea generation rate G	20.59 mg/min
nPNA	1.86 g/kg/day
Fluid balance: Removal	3600 ml/day

* Recommended for more accuracy of clearance calculation

** If Cbi is not constant, use daily average Cbi

*** Need 2 samples of blood and/or ultrafiltrate, preferred 24 hr apart

Which index of adequacy?

DAILY CLEARANCES WITH DIFFERENT TECHNIQUES

EKR_jc

(A generalized form of the EKR_c)

- Based on core equation

$$\text{EKR} = \frac{\text{Continuous Removal Rate}}{\text{Continuous Concentration}}$$

$$\text{EKR}_j = J_m / \text{TAC}$$

Sum (Σ) of net urea mass removed in each RRT over the period (i.e. weekly)

Ratio from AUC of the urea time-concⁿ profile and the duration of weekly interval ($T_0 - T_{wk}$)

$$\text{EKR}_{jc} = \text{EKR}_j / V \times 40$$

CONCLUSIONS

- The process from admission to therapy prescription can be standardized according to guidelines
- Prescription should be made according to patient characteristics, specific targets and available resources
- Effective delivery can be different from prescribed therapy due to several reasons including device or machine dysfunction and treatment downtime.
- Information technology can help to perform a continuous monitoring on effective delivery of therapy

Solutions for Renal problems in this lady

- **CVVHDF was initiated with low volume substitution fluid replacement, net UF of 150ml/h escalating to 350ml/h. Net total UF was 8700ml.**
- **Plasma, packed RBCs transfusion.**
- **CVP started to decline.**
- **UOP increased reaching 100-150 ml/h.**
- **No orthopnea.**
- **Alpha methyl dopa stopped.**
- **Discharge from ICU.**

Thank You
